

Diet & Nutrition Guide

Macronutrient Roles

Macronutrient	Calories/gram	Primary Role	Common Sources
Protein	4	Muscle repair & growth, satiety	Chicken, fish, eggs, dairy, legumes, tofu
Carbohydrate	4	Primary energy source, glycogen replenishment	Rice, oats, potatoes, fruit, whole grains
Fat	9	Hormone production, nutrient absorption	Olive oil, nuts, seeds, avocado, fatty fish

Calorie Balance

Deficit = fat loss, surplus = weight/muscle gain, maintenance = calories roughly equal to TDEE.

A moderate deficit (300-500 kcal) or surplus (200-300 kcal) is generally more sustainable and body-composition-friendly than aggressive swings.

Diet Patterns Overview

Pattern	Core Idea	Considerations
Balanced/Flexible Dieting	Track macros, no foods off-limits	Sustainable, works for most goals
High-Protein	Elevated protein, moderate carbs/fat	Good for satiety and muscle retention
Low-Carb	Reduced carbohydrate intake	May help some with appetite control
Vegetarian/Vegan	Plant-based, no/limited animal products	Needs attention to B12, iron, protein variety
Mediterranean	Whole foods, olive oil, fish, vegetables	Associated with strong long-term health outcomes

Hydration & Fiber

General fluid guidance is often cited around 30-35 ml of water per kg of bodyweight per day, increased with heat and exercise.

Aim for roughly 25-38 g of fiber per day from vegetables, fruit, legumes, and whole grains to support digestion and satiety.

Meal Timing

Total daily intake matters most for body composition; meal timing has a smaller but still relevant effect on performance and recovery.

A meal with protein and carbohydrate within a few hours of training supports recovery and glycogen replenishment.
